34 PORTUGUESE ECONOMY

International economy: the outlook improves as the year draws to a close

As we approach the end of a year characterised by uncertainty and volatility in the economic and financial variables, the sensation is that the global economy is capable of absorbing the effects of the supply shocks, the increase in geopolitical risk and the rising interest rates much better than had been anticipated at the end of the summer. Having confirmed that there was positive growth in Q3 in most major economies (with the exception of Japan and the United Kingdom), the cooling of economic activity in recent weeks is appreciable but less pronounced than anticipated. In particular, the strength of the services sector is managing to offset both the widespread weakening of industry and the initial effects of the interest rate rises on the housing markets with the greatest imbalances. Meanwhile, the decline in agents' expectations also seems to have slowed at a level which, while consistent with a significant cooling in economic activity, does not indicate a widespread recession that would affect employment.

The steady improvement in the bottlenecks since the summer (inventories have recovered) and the moderation in energy prices (both oil and gas) have offered the first respite in a long time in these supply-side constraints, which have been holding back the international economy for the last two years. All this, combined with the continued encouraging tone in the labour market and the safety buffer still provided by the household savings accumulated during the pandemic (1.5 trillion in the US alone), is allowing the slowdown in economic activity to remain contained in the closing weeks of the year. These dynamics are also reducing the risk of stagflation, especially if prices begin to come back down from the peaks reached in the autumn, as seems to be the case, with the incipient correction of the imbalances between global supply and demand.

Such a scenario would allow the central banks to take a break after their December meetings in order to assess what effect the sharpest tightening of financial conditions in recent decades has had on economic activity, financial stability and the pattern of inflation. The monetary authorities have used much of the arsenal of tools at their disposal, yet they do not yet know whether what they have done will be sufficient to achieve their objectives, not least because of the time lag of monetary policy. This pause could lead to a more surgical convergence on the terminal rate, which could be below that expected by the markets. That said, we cannot yet rule out the potential need for a new phase of rate hikes if the inflationary pressures intensify once again or if inflation expectations need to be kept in check. For the time being, it is also worth pointing out that, with much of the work done, the monetary normalisation process is taking place without major financial accidents (except for the British mini-crisis), even in emerging markets, despite high global debt levels.

The good news, therefore, is that the central forecast scenarios laid out after the summer look increasingly likely to materialise, most of which anticipated a stagnation in economic activity over the winter but not a recession with job destruction linked to energy rationing in northern Europe. A large part of these scenarios envisaged higher oil or gas prices at this point in the year compared to where they stand today, which means there is some leeway in the forecasts for potential negative surprises. In this regard, although winter still lies ahead and it is too early to declare victory on the energy front, the risk profile also seems to be shifting as more attention is being focused on the effects of China's zero-COVID policy being brought to an end, without forgetting possible complications in the final stages of the monetary normalisation process. Most importantly, after what has been a very difficult year, it seems we will end it in better shape than could have been expected just a few months ago, with the supply-side shocks beginning to weaken. Let us hope that will be the tone throughout 2023.

José Ramón Díez

---	--

The indicators provide a respite

The main indicators concerning the Spanish economy have improved slightly during the last month. This alleviates fears of a sharp decline in economic activity and, indeed, opens the door to the possibility of the year ending without a contraction in GDP. In addition, the good news has come in a number of areas. In any case, the pressure on economic activity, and especially on household consumption, will remain high until there is a sustained reduction in inflation. The rapid rise in interest rates by the ECB will also limit the economy's ability to recover over the next few quarters.

At the sector level, the improvement has occurred in both manufacturing and services. The composite PMI rose in November to close to 50 points, the threshold which usually separates positive growth rates from negative ones. Industrial production performed particularly well, maintaining a positive growth rate in year-on-year terms in spite of the adverse context. In the services sector, meanwhile, retail sales improved significantly, registering a positive growth rate in October and the highest year-on-year rate of change in the last five months. There were also encouraging signs in this area from consumer confidence; while still low, in October it improved for the first time in a year and a half.

However, among all the positive news, two particular developments stand out: the fall in the inflation rate and the strength of the labour market. An easing of the inflationary pressures was already expected to occur in the closing stages of the year, but the shift is proving rather more pronounced than expected, primarily thanks to the moderation in electricity prices. The recovery of renewable energy production, the reduction in the price of gas on the international markets, as well as the increased efficiency of the gas price cap (thanks to the decline in gas-fired electricity production and the increase in the number of consumers paying the compensation surcharges), have been the key elements to date. Looking ahead to the coming months, the moderation in the inflationary pressures is expected to continue, and this should facilitate the consolidation of the incipient improvement in consumer confidence, which has been severely hampered to date.

With regard to the labour market, job creation remains highly buoyant. Following the encouraging figures for November, the growth in the number of people in employment in Q4 could end up at around 0.5% quarter-on-quarter (0.7% in Q3), representing a more moderate

slowdown than had been expected. In previous episodes of economic weakness, the slowdown in employment tended to be more abrupt. Indeed, in a context like the current one, there would most likely have been some job destruction by now. However, the successive reforms of recent years, which have reduced the incidence of temporary employment and have favoured the adjustment of working hours over the course of the business cycle, could have led to a structural change in how the labour market behaves.

The impact of all this is not inconsiderable. The reduction in household incomes, in real terms, has been significant, but the way this impact has been distributed among the population is very different from previous crises. Specifically, household gross disposable income this year will likely have fallen by around 6% from the peak reached in Q3 2021. This is a significant figure. To put it in context, it represents almost half of the decline that occurred during the financial crisis, which amounted to 14.6%. However, a decade ago the bulk of the adjustment was concentrated among the portion of the population that lost their jobs. The sharp rise in the unemployment rate, which peaked above 25%, has been etched into everyone's memory. This time, in contrast, the resilience of the labour market is allowing the impact of the crisis to be transmitted more evenly among the population.

Thus, despite the current difficulties, wage income inequality has continued to decline in recent months. In October, the real-time Gini Index produced by CaixaBank Research was just 1 point below the pre-pandemic level. Even among the most vulnerable groups, such as young people or those born outside Spain, who often suffer the most in contexts like the present, inequality continues to decline, and it is also well below the levels registered in 2019.

In short, despite the uncertainty surrounding the current context and the difficulties faced by many households and businesses, the economic indicators at the close of the year offer a glimmer of hope.

■ Forecasts

Autumn rally in the financial markets

Investor optimism consolidates in November. As was the case in late October, the performance of risk assets was driven by a positive tone among investors during much of November. Some of the main factors behind this optimism included signs of moderation in the inflationary tensions, the somewhat less pronounced slowdown in economic activity and the tentative stabilisation of the energy markets, as well as the confirmation that the trajectory of fiscal policy in some countries (such as Italy and the United Kingdom) looks set to remain in line with monetary policy objectives. Even in China, which is facing a difficult health situation, the authorities gave slight glimpses of a possible relaxation of its zero-COVID policy. In this context, the major central banks appeared to be in favour of reducing the pace of monetary tightening. In the financial markets, expectations of a possible pivot in monetary policy triggered a rally in international stock markets and in fixed-income assets, as well as a depreciation of the dollar. This optimism helped to reduce the cumulative losses in the year, albeit in a highly uncertain and volatile environment.

The Fed could adopt a less aggressive stance. The minutes of the FOMC's November meeting reflected a somewhat more relaxed tone regarding the future path of monetary policy. The Fed members supported further rate hikes at the upcoming meetings, but were open to a reduction in the pace of the increases after having already introduced four consecutive 75-bp rises. This «pivot» to a less aggressive stance was corroborated by Jerome Powell himself, who stated that there could be a change in the pace of monetary tightening as soon as the December meeting. However, Powell also warned that, despite the slight yield in inflation, it remains very high and the labour market is showing little sign of slowing down, which justifies further interest rate hikes (alluding to the possibility of keeping rates somewhat higher and for a little longer). Nevertheless, the financial markets are assuming that the Fed will slow the process of rate hikes in December (with a 50-bp increase up to the 4.25%-4.50% range), and that by the end of 2023 it will once again stand at around 4.50%, almost 0.5 pps lower than that forecast in October. This shift in expectations contributed to the reduction in US sovereign debt yields from the highest levels of the year. In November, the yield on the 10-year bond dropped by more than 40 bps, to around 3.6%, while in the case of the 2-year bond it fell by around 20 bps, to around 4.3%.

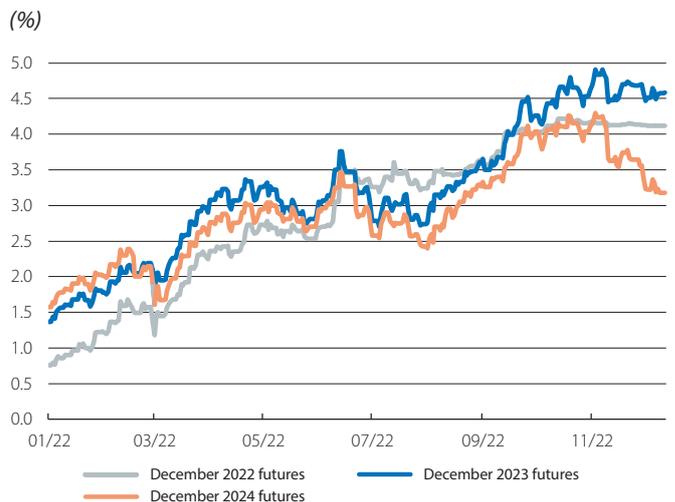

The ECB also hints at further rate hikes, but at a slower pace. In the euro area, the minutes of the monetary authority's meeting showed its members' support for the 75-bp interest rate hike implemented in October. With regard to the forthcoming meetings, however, it was clear that opinions were divided over how to manage the tightening of financial

conditions in a scenario marked by inflation that remains very high and the emergence of downside risks to economic activity. Nevertheless, just as in the US, the markets anticipate a moderation in the cycle of rate hikes in the upcoming meetings, with a 50-bp increase expected at the December meeting (bringing the depo rate to 1.00% and the refi rate to 2.50%). This movement led to a widespread decline in euro area sovereign debt yields in the long sections of the curve, albeit to a lesser extent than in the case of US debt.

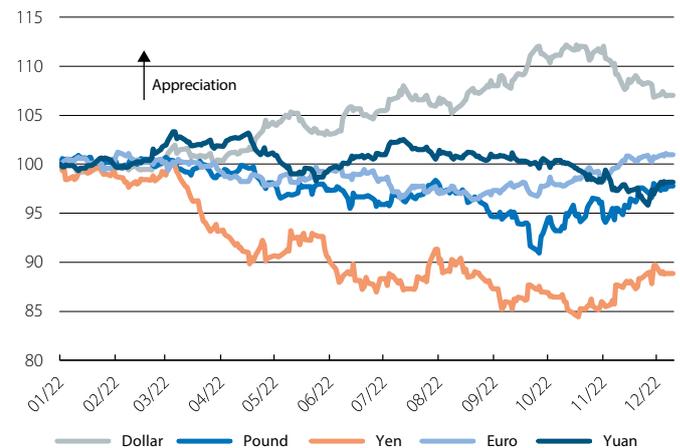

The dollar offers a respite. The spread of risk-on sentiment, driven by the optimism in the financial markets mentioned earlier, eased the buying pressure on the dollar which it had been experiencing since Q2 with the beginning of the Fed's rate hikes and the outbreak of war in Ukraine. This favoured the appreciation of the euro, which consolidated its exchange rate above parity against the dollar. The pound sterling also appreciated significantly against the dollar, by more than 5% in November, reflecting a good reception among investors regarding the fiscal measures announced by the new prime minister Rishi Sunak.

Oil and gas prices drop. Uncertainty surrounding future crude oil demand in a context of slower economic growth led to the oil price falling by 10% in November. This trend was reversed in early December as a result of the emergence of signs of a possible relaxation of the health policy in China, the start of the EU embargo on Russian crude oil (see the Focus «[Europe and the mission to decouple from Russian oil: an achievable goal in the short-term](#)» in the MR10/2022) and the imposition of a price cap on Russian oil by the G7. Specifically, the EU and the G7 agreed not to buy Russian oil transported by sea above 60 dollars a barrel. This measure came into force on 5 December, although an extension is given until 19 January for vessels that were loaded before that date. The European gas price, meanwhile, fell once again in November on average, favoured by the high levels of inventories amassed by the EU and a relatively warm autumn. However, in late November and early December, gas prices began to climb as temperatures fell in Europe.

The improvement in investor sentiment supports a stock market rally. For the second consecutive month, the major stock market indices performed well and recovered some of the losses accumulated during the year. In addition to the factors mentioned above, this improvement was also favoured by the end of the Q3 business earnings campaign, which resulted in a higher balance of profits than that expected by the consensus of analysts. The gains also extended to the emerging country indices, with the MSCI Emerging Markets index closing November up around 15%. Part of this rally was due to the gains registered in China's stock markets, which benefited from government measures aimed at supporting the real estate sector, as well as expectations of a less stringent approach to COVID that would favour the Asian giant's economic recovery.

The impact of higher agricultural commodity prices on emerging and low-income countries

After several years of stability, international food prices peaked in the spring of 2022 following the outbreak of the war in Ukraine. The rally began in Q4 2020 and intensified in 2021 with the increase in energy prices, disruptions to global supply chains following the pandemic and extreme weather events that reduced harvests. Subsequently, between March and May of this year following the invasion of Ukraine, prices rose to record highs due to the disruption in the flows of agricultural commodities from two of the world's leading exporters.¹ Today, almost 10 months after the start of the war, a large part of the trade flows through the Black Sea have been restored,² while fears about interruptions in basic food supplies have also subsided. As a result, prices of agricultural goods, particularly cereals, have fallen since that peak reached in the spring (wheat by more than 40% and corn by around 20%), despite still remaining around 30% above the average for the last five years.

However, the relative improvement in international prices of agricultural goods has barely been reflected in global consumer prices. The main reason for this is the depreciation of many countries' currencies against the dollar. In particular, this depreciation intensified with the Fed's first interest rate hike, and it has led to higher commodity prices in local currencies relative to their US-dollar price.³ As an example, while the price of corn went from 650 to 789 dollars per bushel between February and May, the price in Turkish lira rose from 9,014 to 12,592 over the same period. This aspect also helps to explain why the upward pressure exerted by domestic food prices on countries' inflation rates has persisted.

The surge in agricultural prices does not affect all countries alike

Rising food prices, coupled with rising energy prices, have eroded consumers' purchasing power over the past 12 months around the world. But the impact has not been the same in all countries. According to the IMF,⁴ food products account for a larger portion of consumer

1. According to data from the Food and Agriculture Organization of the United Nations (FAO), Russia and Ukraine account for a quarter of the world's wheat exports, one fifth of barley and corn exports and over half of sunflower oil exports, and they supply around one-eighth of all the calories traded in the world.

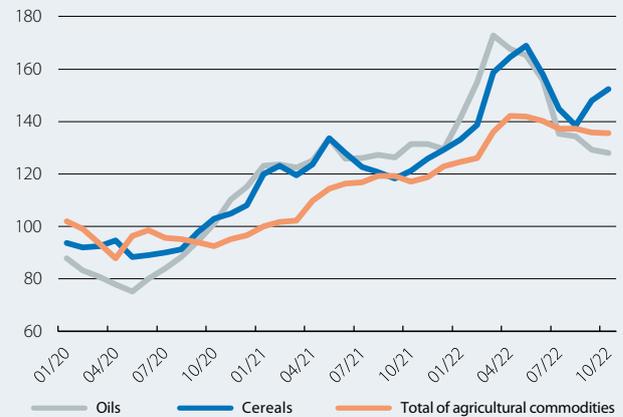

2. The [Black Sea Grain Initiative](#) signed between the United Nations, Russia and Ukraine in July 2022 has allowed Ukraine to export over 11 million tons of agricultural goods by sea to date since August.

3. Since the 1980s, most commodities are traded in international markets in US dollars.

4. See IMF (2022). «[Fiscal Policy for mitigating the social impact of high energy and food prices](#)» (June).

spending in low-income countries than they do in high-income countries. Whereas in the former the average expenditure on food reaches as high as 44% of disposable income,⁵ in emerging economies this percentage is around 28% and in developed economies it drops to 16%. This uneven distribution has been reflected in the significant increase in inflation rates in lower-income countries and in some emerging countries, reaching double digits in most cases. In addition, the support from governments to limit the negative impact of price increases on real incomes has also been uneven. The fiscal effort of emerging and lower-income countries during the pandemic has significantly reduced the scope

5. Low-income countries are found all around the world, although sub-Saharan Africa is where the largest number of these countries are concentrated.

for action of their fiscal policies. So far this year, 44% of these economies have implemented price measures, compared to 84% in the case of advanced economies.

The surge in food prices in the group of less-favoured countries not only has an impact on inflation, but also extends to other areas of the economy and highlights their vulnerability to the volatility of international food prices. At the macroeconomic level, the price rally leads to a decline in the rate of growth.^{6,7} In addition, as observed in the food crisis of 2008-2009, rising food costs tend to coincide with episodes of currency weakness, and this accentuates the tightening of domestic financial conditions and exacerbates the trade deficit in these countries (75% of emerging and low-income countries are net importers of agricultural commodities). At the microeconomic level, rising food prices reduce households' purchasing power, lead to greater social inequality (in terms of access to food), and exacerbate poverty.

Food security: a key issue

The World Bank estimates that international prices of agricultural commodities will fall by an average of 5% in 2023, as a result of the gradual return of export flows from Ukraine and the moderation of demand in the context of a slowdown in the global economy, before later stabilising in 2024. However, despite this dynamic, prices of the main cereals (wheat, corn and rice) are expected to remain above their historical average, in view of the fall in global grain production between 2022 and 2023, which could reach 2.3% (57 million metric tons) according to the US Department of Agriculture.

Nevertheless, in the face of high geopolitical and economic uncertainty, there are risks that could lead to further price rallies. In addition to the war in Ukraine, which could lead to a fall in Ukraine's agricultural production of up to 45% between 2022 and 2023, these risks also include: the persistence of inflationary pressures worldwide, the appreciation of the dollar, continued high energy costs – not only crude oil and natural gas, but also fertilizers –, the diversification towards crops for biofuel generation, the restrictive trade policies of some exporting countries in an attempt to control domestic prices, and increasingly extreme weather events such as La Niña.

Moreover, rising food prices – accentuated by the war – have contributed to an increased risk of food crises in many emerging and low-income countries (especially in

6. See World Bank. «[Commodity Markets Outlook. Food Price Shocks: Channels and Implications](https://www.worldbank.org/)» (worldbank.org).

7. The exception to this trend is observed in net commodity exporting countries. For example, Brazil is one of the five largest net exporters in the world. Exports of agricultural goods account for 37% of its total exports and grew at a rate of 9.4% per year over the last two decades.

Trade: countries prohibiting exports of agricultural goods

sub-Saharan Africa, the main importers of Russian and Ukrainian grain), as well as accelerating the process of food insecurity⁸ in certain parts of the world (led by sub-Saharan Africa, Eastern Europe, Central Asia, and Latin America). In addition to posing a serious humanitarian problem,⁹ this aspect could slow these countries' economic growth in the medium term.

Beatriz Villafranca

8. According to the FAO, food insecurity occurs when people do not have regular and permanent access to food of sufficient quantity and quality to survive.

9. Estimates by the Food Security Information Network suggest that over 200 million people around the world were in a situation of food insecurity as of September 2022.

The big data dependence of the markets and monetary policy

In 2022, the central banks have implemented aggressive interest rate hikes in a pattern not seen since the 1980s. More stealthily, another monetary policy tool has had an equally virulent impact on the financial markets: communication. We only have to go back to 10 November 2022. At that session, the 10-year US sovereign interest rate collapsed by 30 bps, marking its biggest daily decline since 2009 and the second sharpest in the last 35 years. The cause, a seemingly harmless surprise: the US inflation figure for October, at a high 7.9% year-on-year, was 2 percentage points lower than expected by the analyst consensus. Those 2 percentage points, however small, reverberated through the international financial markets.¹ After all, given the uncertainty in the current economic environment and the reorientation in central banks' communication tools, investors are hungry for information that can help them get a sense of what monetary policy might do next.

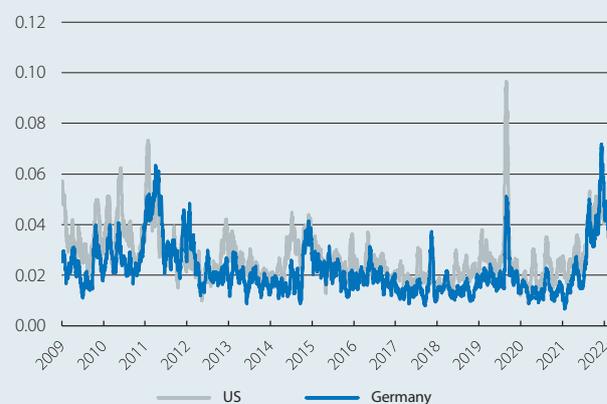

Monetary policy communication: a tool being reoriented

This communicative reorientation has gone through three phases. At the end of 2021, the central banks were still giving fairly explicit messages about what path interest rates would take, and they did so in both the short and the long term. At the beginning of 2022, under pressure due to the persistence and intensity of the inflation rally, they became explicit about their intention to aggressively raise interest rates at their upcoming meetings. Finally, in recent months, the explicitness has once again waned: the latest messages continue to point towards further rate hikes, but highlight the uncertainty of the environment and advocate a more flexible approach to decision-making.

As an example, in late 2021, the US Fed stated that it was appropriate to maintain a dovish monetary policy until the labour market reached full employment and inflation was slightly above 2%, exceeding this level for quite some time. In Europe, the ECB adopted a similar strategy: it would keep rates at historical lows until 2% inflation was projected on a sustained basis (which, according to market rate expectations, would still take 1 to 2 years to occur). In 2022, they quickly changed course, but the message on rates remained relatively explicit: the Fed raised rates in March and declared that it would continue to do so over the coming months, while the ECB began to signal the same message between June and July. Thus, they will have ended 2022 with cumulative increases of more than 400 and 200 bps, respectively. At this point, both institutions are still indicating that further rate hikes lie ahead, but that automatic pilot has been disengaged and decisions will be taken «meeting by meeting» and be «data-dependent».

1. There was a high degree of contagion to the interest rates of other countries. For example, in Germany the 10-year sovereign rate fell by more than 15 bps, while Spain's rate dropped by 20 bps and Italy's collapsed by almost 30 bps.

Daily fluctuation of the 10-year interest rate 30-day moving average (pps)

Germany: sensitivity of sovereign rates to domestic inflation surprises*

(p. b.)

Note: * The sensitivity corresponds to the coefficient β estimated in 30-month windows using the regression $\Delta i_t = \alpha + \beta(\pi_t - \pi_t^e) + \varepsilon_t$, where Δi_t is the daily fluctuation of the interest rate, π_t is the observed inflation figure, and π_t^e is the inflation expected by the Bloomberg consensus.
Source: CaixaBank Research, own calculations based on data from Bloomberg.

All this results in less predictability – an approach that is necessary for monetary policy to respond quickly and appropriately to developments in the economic environment, but which accentuates uncertainty and helps to explain the heightened volatility in market interest rates (see first chart).^{2,3}

Market sensitivity

The Fed and ECB are putting the evolution of the data at the forefront of their upcoming decisions, especially developments in inflation – hence the market's hypersensitivity on 10 November. But this sensitivity is

2. Relative measures of volatility (i.e. taking into account the starting level of interest rates) have also settled in 2022 at above pre-pandemic levels (e.g. the coefficient for the fluctuation of the US rate is 90% higher than the average for the period 2017-2019).

3. A complementary explanation for the higher volatility in interest rates is the lower liquidity in various bond markets, such as in the Treasuries market. See Michael Fleming and Claire Nelson, «How Liquid Has the Treasury Market Been in 2022?», Federal Reserve Bank of New York Liberty Street Economics, 15 November 2022.

not a one-day anecdote: it has steadily increased throughout 2022.

As we see in the second and third charts, the interest rates on 2- and 10-year debt in recent months have become more reactive to inflation surprises in both Germany and, above all, the US.⁴ Also, as the fourth chart shows, the sensitivity of German interest rates to surprises in the US inflation data has also been increasing, showing what appears to be a stronger correlation between the US treasury and the German *bund*.⁵ One consequence of this volatility in rates is that caution must be exercised when trying to infer market expectations on the basis of prices in the financial markets: beyond monetary policy expectations, these interest rates are likely to incorporate risk premia due to the uncertainty regarding the current environment.

Similarly, in the last chart we can also see how the sensitivity of other types of assets in 2022 has been very different to the average observed in other periods. Particularly pronounced is the change in the sensitivity of the US stock market to inflation surprises: not only has it increased (in absolute terms), but it has also changed sign. One possible explanation for this shift is that, whereas inflation above the consensus expectation in the period 2016-2021 could signal a more dynamic economy, and thus a better outlook for corporate earnings, a similar surprise today implies the expectation of a more restrictive monetary policy, with the associated negative impact on growth and stock-market performance.⁶ On the other hand, the negative sensitivity of the exchange rate is consistent with the fact that higher-than-expected inflation causes the dollar to appreciate due to the expectation of rate hikes in the US.

Finally, it is important to note that surprises in the inflation statistics impact short-term inflation expectations (identified in this case by inflation swaps for the next two years), while they do not appear to have any significant impact on medium- and long-term expectations (identified by the 5-year, 5-year inflation swap). This shows that, despite an exceptional economic and financial environment and high inflation, the central banks are managing to uphold their credibility and keep inflation expectations close to the 2% target.

Ricard Murillo and María Suárez Marañón

4. In these exercises, the estimated sensitivity corresponds to the coefficient β of the regression $\Delta i_t = \alpha + \beta(\pi_t - \pi_t^e) + \varepsilon_t$, where Δi_t indicates the change in the interest rate on the sovereign bond (US and German 2- and 10-year bonds) on the day the inflation data is published, π_t is the observed inflation (the flash indicator in the case of Germany) and π_t^e is the inflation expected by the Bloomberg consensus. We estimate the regression using data from the 30 months prior to t and we show the value of the parameter β over time.

5. One possible interpretation of this stronger correlation is that the markets read the US signals as clues about the future of Europe.

6. As for sovereign risk premia, in 2016-2021 they tended to narrow in response to higher-than-expected inflation, while in 2022 no significant response is apparent.

Stagflation or permacrisis?

Geopolitical shock: a higher-risk environment on the horizon.

In recent months, we have seen both supply- and demand-side shocks multiply, resulting in an economic scenario with higher inflation and lower growth than we were anticipating a few quarters ago. The legacy of the pandemic – bottlenecks, pent-up demand and a recovering labour market – has been compounded by the outbreak of the war in Ukraine, the resulting energy shock and restrictive monetary policies, with the fastest cycle of interest rate hikes in decades in economies such as the US and the euro area. In this environment, the word stagflation re-entered our lexicon. However, what perhaps better defines the current environment is the high degree of uncertainty and an international context in which geopolitical tensions have returned to centre stage. So far this year, the geopolitical risk (GPR) index has reached 160 points. Since 1985, on an annual average, only between 2001 and 2003 had the index exceeded 150 points. So it is no surprise that the British Collins dictionary has named «permacrisis» (an extended period of instability and insecurity) as the word of the year.

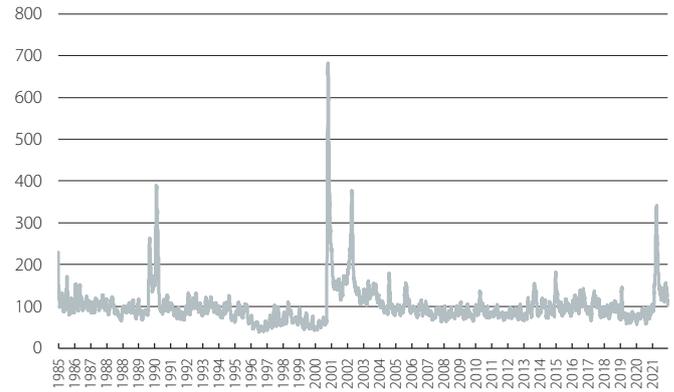

Energy shock: persistently high gas prices. One of the main factors shaping the current scenario is the energy crisis. In November, the average spot price of gas per the main European benchmark (TTF) fell to €118/MWh (-15% compared to October). This moderation was supported by the high levels of reserves across the EU, which were at around 92% of capacity at the end of November (compared to an average level at the same time of year of 82% over the last five years), as a result of the high substitution of imports and reduced consumption. However, this decline occurred in a month with relatively warm temperatures and, in any case, prices are still 44% higher than a year ago and six times higher than the historical average (around €20/MWh). In addition, futures contracts continue to point to prices above €100/MWh in the next two years, suggesting that the high energy prices will continue to constrain business and household activity.

Inflationary shock: is the peak finally behind us? As a result of the moderation in energy prices, headline inflation in the euro area stood at 10.0% in November (versus 10.6% in October), the first decline since mid-2021. Core inflation (excluding energy and food) remained stable at 5.0%. In the US, inflation continued to moderate in October (the latest available data), with the headline index falling to 7.7% (versus 8.2% in September) and the core index down to 6.3% (6.6% in September). This cooling of inflation may support a moderation in the pace of the interest rate hikes by the Fed and the ECB. It is still too early to declare that inflation has peaked, and there will likely be volatility in the data, but we can expect to see a gradual moderation during the course of 2023. In particular, the base effects themselves, the greater stability of energy prices, the easing of the bottlenecks, the cooling of economic activity and the limited second-round effects should, on the whole, allow for a correction of the imbalances between supply and demand and, thus, support a gradual reduction in inflation next year.

Supply shock: the downside risks have moderated. In the euro area, the composite PMI figure (47.8 in November versus 47.3 in

Global: geopolitical risk (GPR) index

October) was better than expected, albeit consistent with a slight contraction in GDP in Q4. The improvement was concentrated in the manufacturing PMI (which climbed from 46.4 to 47.1 in November), which could reflect the normalisation of supply chains. On the other hand, the services PMI remained unchanged, and also in contractionary territory (48.6 points). The publication of the Ifo Business Climate Index for Germany in November underscores this same message. Despite a slight increase in November (from 84.5 to 86.3 points), the data are consistent with a decline in economic activity. On the other hand, in the US, the data also showed signs of a cooling in activity. In particular, the manufacturing ISM in November was below 50 points for the first time since May 2020, while in the labour market the pace of job creation slowed to 263,000 jobs, a relatively high figure but lower than in October.

Food shock: emerging economies in a vulnerable situation.

As the World Bank recently pointed out, food price inflation has exceeded headline inflation in 90% of the 156 countries with available data. Developing and emerging economies are particularly vulnerable, with around 90% of them experiencing food inflation in excess of 5%. Despite the recent price moderation, the risks remain high. The deterioration in the geopolitical environment, and the war in Ukraine in particular, is the number one concern. However, the global environment of higher inflation and higher interest rates is also a major source of risk, as it exerts upward pressures on food costs due to the higher commodity prices, wages, and capital costs. The World Bank also notes that the percentage of the world's population in a situation of food insecurity will continue to rise, exacerbating all the adverse effects which such a situation generates in the long term.

Succession of shocks in China: the health restrictions will continue to hold back the economy. Economic activity in China continues to show signs of weakness in Q4. As the country struggles to contain the largest new outbreak of COVID-19 cases since the beginning of the pandemic, and while the authorities are debating the zero-COVID policy, economic activity is showing clear signs of slowdown. China's official composite PMI suffered its fifth consecutive fall in November, dropping to 47.1 points (versus 49.0 in October). In addition, the latest surge in cases is the one that poses the greatest risks since the first wave due to its geographical extension: over 100 cities have reported cases in recent days (compared to around 50 in April). The low level of vaccine coverage, coupled with the lack of capacity in the health system, make it difficult to imagine a steady reopening of the Chinese economy over the coming months (see the Focus «China's symptoms: more than COVID» in this same report). Although signs have emerged of a concerted effort to introduce flexibility into the country's health policy, there is still a long way to go. The low immunity of the population poses a major obstacle for the sustained reopening of the economy, and relatively severe restrictions are most likely to be required to contain the pressure on the health system in the short term. Moreover, the experience of the reopening process in other Asian countries shows that mobility rates take over six months to return to normal.

China's symptoms: more than COVID

China is facing a particularly challenging economic environment. The combination of a housing crisis and slowing global demand – two major drivers of China's growth in recent decades – has been joined by a third force, which over the last two years has been shown to have significant potential to distort the economy: the zero-COVID policy. The authorities' response to new outbreaks of the pandemic continues to involve recurrent lockdowns in some of China's biggest cities, as well as shop closures and inciting greater caution among Chinese consumers, which increases the volatility of the economic environment. As a result of these three forces, China's economy is expected to grow by around 3% this year, the lowest rate in almost half a century (with the exception of 2020, when the Asian giant grew by 2.2%). In the medium term, economic growth also looks set to experience a slowdown. The 20th National Congress of the Communist Party of China (CPC) has shed some light on the «black box» of Chinese politics and the top priorities for the next five years.

Symptom 1: zero-COVID or growth problems?

The indefinite extension of China's zero-COVID policy can be understood as the result of three main factors: the more limited capacity of the country's health system to cope with a possible wave of infections after the reopening of the economy, the low rate of effective

vaccination, and the political narrative, which throughout this period has repeatedly underlined the success of China's strategy in avoiding the high levels of mortality observed in other countries.¹ Thus, in the short term, the variable that could lead to a sustained softening of the zero-COVID policy is progress in the vaccination rate, also taking into account the reinforcement of the official discourse in support of the current health policies.

As of the first half of November, 57% of the population in China had received three doses, compared with a two-dose coverage of 73% of the population in the EU and 69% in the US.² Moreover, among the elderly population (over 80 years of age), this figure is estimated to be 40%, well below the threshold that allowed the sustained reopening of the economy in other Asian countries (all with vaccination rates exceeding 90% among the elderly population when restrictions were lifted). Finally, the speed of the vaccine roll-out has shown signs of stagnating in recent months (with a daily vaccination rate of 0.01% of the total population, compared to an average of around 0.5% in the winter of 2021). In short, beyond periodic adjustments to the zero-COVID policy, this factor can be expected to continue to pose a significant constraint on the Chinese economy throughout 2023, whether because of the need for new «forced» lockdowns in the event of a lifting of the restrictions (to avoid excessive pressure on the healthcare system) or

Notes: For the BRICS countries (Brazil, Russia, India, China and South Africa), the ASEAN countries (Brunei, Cambodia, the Philippines, Indonesia, Laos, Malaysia, Myanmar, Singapore, Thailand and Vietnam) and the euro area (Germany, Spain, France and Italy), we use weighted averages based on each country's population. For all countries, we use the average for the period 2015-2019 or the latest available data up to 2019 at the time the exercise was performed. The Gini Index is a measure of inequality and can take values between 0 and 100. Higher figures denote higher levels of inequality, and vice versa. Total consumption is the sum of final household consumption (private consumption) and final public consumption.

Source: CaixaBank Research, based on data from the World Bank and the OECD (Global Revenue Statistics Database).

1. The official COVID-19 mortality figures in China show a cumulative mortality rate of 0.4 people per 100,000 inhabitants, one of the lowest in the world (e.g. 37.6 in Japan, 257.8 in the EU, 316.3 in the US and 31.6 for Asia as a whole). Comparing estimates of excess mortality over the period, China would still be in a «leadership» position, albeit somewhat less far ahead: between 3 and 190 excess deaths per 100,000 inhabitants in China, versus 81-99 in Japan, 330-340 in the EU, 370-410 in the US and 160-380 on the Asian continent. See *The Economist* (2022), «The pandemic's true death toll» (consultation date: 31 October 2022).

2. The technology used in the vaccines administered in China is considered to be less effective. Therefore, it is estimated that three doses of these vaccines are required in order to achieve the degree of protection equivalent to two doses of the mRNA vaccines predominantly used in the EU and the US.

due to a continuation of the strategy to try and eliminate the virus.

China's current health policy must be framed in a broader context. Although China has been the driver of global growth over the last two decades, it is still a middle-income country, with a GDP per capita of around one-third of the euro area average (in purchasing power parity terms) and a quarter of the level of the US (see table). In this context, although health expenditure has been increasing in recent years, it is still substantially below that of more developed countries, and the basic healthcare infrastructure (measured in terms of hospital beds or doctors per patient) is also more limited, albeit with better rates than other emerging countries such as the rest of the BRICS or ASEAN blocs.

Specifically, the US leads the way in current health expenditure, although almost 50% of this is private expenditure and the high figures also reflect the high costs at which the health system operates in this country (private expenditure encompasses direct household expenditure on health products or services, expenditure by private insurance companies and by the social sector). In euro area countries or Japan, health expenditure is around 10% of GDP, and private expenditure accounts for less than 25% of the total. In China, in contrast, not only is the total health expenditure lower, but 40% of it is private, with a significant fraction being direct household expenditure (35% of the total health expenditure). Together, these figures suggest a healthcare system still in a development phase, with a significant fraction of the population having limited access to healthcare.

Symptom 2: low private consumption or lack of a social safety net?

The low level of public healthcare expenditure is also related to the limited scope of China's welfare state. The relative weight of the state in the economy, measured by tax revenues as a percentage of GDP, is less than 20% (compared to over 30% for the OECD as a whole). This leaves a large portion of the population without a social safety net of healthcare, social benefits, unemployment benefits or pensions.³ This factor is also key for explaining the country's persistently high savings rate, which is around 45%.

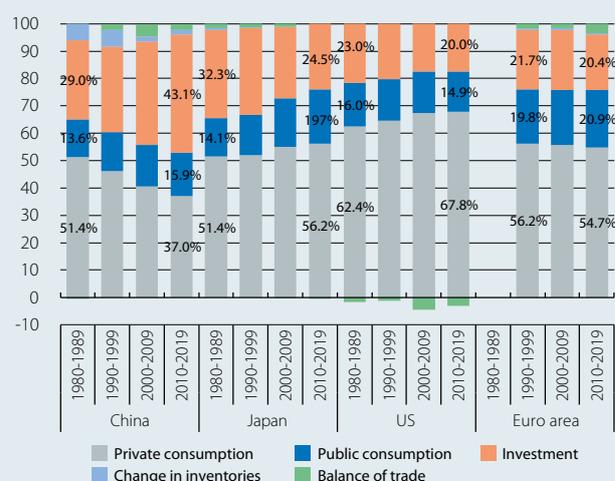

Similarly, China has one of the lowest levels of consumption in the world (55% of GDP, less than 40% of which is private consumption)⁴ and a high level of investment (see chart). While these factors have been

3. In addition, the citizen registration system establishes a clear division of rights between rural and urban populations. The granting of *hukou* status determines a citizen's access to a wide range of benefits and social services in urban areas, such as healthcare, public education, the pension system, and eligibility for bank loans.

4. In emerging countries, on average, total consumption represents 65% of GDP. In advanced economies, it represents 75% or more of GDP. Generally speaking, private consumption accounts for between 50 to 60% of GDP.

GDP by component

Relative weight (%)

Note: The breakdown of GDP by component uses an expenditure-based (or demand-based) approach, whereby the calculation of a country's GDP is the result of the sum of the components of private consumption, public consumption, investment, the balance of trade and the change in inventories.

Source: CaixaBank Research, based on data from the OECD.

behind the economy's rapid growth in recent decades, today, with the momentum associated with the process of capital accumulation and convergence with advanced economies having run out of steam, they are restricting the buoyancy of economic activity.⁵

China's current symptoms thus go beyond its zero-COVID policy and are the result of deeper imbalances in its economic development model. Experience shows that there is no «vaccine» for escaping the famous middle-income trap.⁶ At the recent Congress of the CPC, President Xi renewed his pledge to pursue a vision of «shared prosperity» and to transform China into a «medium-developed country» over the next 15 years. However, the growing focus on issues of security and self-sufficiency entails further risks for the country's long-term potential growth, in addition to the demographic challenge and the risk of global economic fragmentation. The long-term health of the Chinese economy will depend on the quality of the treatment it receives, its success in rebalancing the growth model, and its ability to embark on a transition to higher value-added activities.

Luís Pinheiro de Matos

5. In turn, the limited international mobility of capital in the country and a less developed financial system have led to a low average return on investment and have contributed to the current housing bubble (due to the housing market being used as a savings tool).

6. The middle-income trap refers to a situation in which a country in the process of economic convergence can no longer compete internationally in the production of more labour-intensive goods, but it also cannot compete in higher value-added activities because it is still far from the technological frontier and has relatively low productivity levels.

Changes in the US Congress: a castling until the presidential elections?

In the midterm elections on November 8th, a red wave was anticipated, with the Republican Party hoping to control the House of Representatives and the Senate and thus gain full control of Congress. High inflation, the somewhat gloomy economic outlook for 2023, and Joe Biden’s low approval ratings (at 37% compared to 55% in early 2021) filled the Republican Party with optimism. Yet the final outcome of the vote produced a somewhat different scenario to what members of the «Grand Old Party» (GOP) had expected.

In the House of Representatives, where 100% of the seats were put to the vote, the Republicans gained control of the House, albeit by a narrower margin than anticipated in the polls. But in the Senate, where 35 out of the 100 seats were up for election, the Democrats managed to take the Pennsylvania vote from the Republicans and thereby secure a majority in the upper house with 51 of the 100 seats (assuming that the two independent members elected in Vermont and Maine continue to caucus with the Democratic vote plus the tie-breaking vote of the president of the Senate, Kamala Harris).

The Biden administration may have difficulty passing new laws and fiscal plans

With a divided Congress, and in a highly polarised political environment, it seems unlikely that Joe Biden’s government will be able to push through proposals that drift far from the centre of the political spectrum. Not only that, it could also have difficulties in pushing through basic measures such as raising the debt ceiling – the limit above which the country’s Treasury cannot issue new debt to finance the federal government, which could potentially be binding in Q3 2023. If this figure is reached without Congress raising the ceiling or suspending the requirement to comply with it, then the administration will have no choice but to call a

government shutdown. It would not be the first time, and the experience of the last shutdown between December 2018 and January 2019 suggests that it would have a clear negative impact on economic growth, as well as generating financial reverberations that would be most undesirable at such a delicate time in the financial markets.¹ However, previous experiences also show that a will among both parties to avoid such consequences ends up steering the situation to be unblocked when an increase in the debt ceiling is agreed upon in exchange for concessions in other areas. Also, should the US economy fall into recession, which is not our central scenario, one would expect the two parties to reach some sort of agreement, however minimal, in order to mitigate the adverse impact on households, while also saving face for the presidential elections in November 2024.

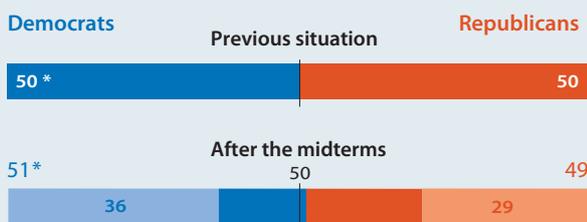

Other aspects in which this division of the chambers could have an impact include the presidential appointment of public officials and the supervision of the president’s executive branch. In relation to the first aspect, Democratic control of the Senate will most likely facilitate the process of the presidential appointments that must be made over the next few years, which are particularly important in the judicial sphere. On the other hand, Republican control of the House of Representatives, while not allowing the GOP to introduce new laws, could be used to further scrutinise the Biden administration. While this supervision is not expected to paralyse what has already been approved in the houses, it could slow some procedures down, although the impact of this would likely be more cosmetic than substantive.

Despite the absence of major plans looking ahead, Biden’s term in office will still have been active in a context of high inflation and public debt

In the nearly two years he has been in the White House, President Joe Biden has been active in implementing

1. According to estimates by the Congressional Budget Office, GDP in Q4 2018 and Q1 2019 was 0.1% and 0.2% lower than it would have been in the absence of the government shutdown.

fiscal and stimulus plans, even though Democratic control of both houses was no guarantee of a smooth path to passing them. Therefore, a divided congress represents more of a gradual change than a disruptive one relative to the previous situation. Some of the most significant plans he has introduced include the American Rescue Plan, approved in Q1 2021, which allocated 1.9 trillion dollars (the majority disbursed in 2021) to help cushion the impact that the pandemic was still having on many households. Most of the measures included in this package were direct expenditure, such as stimulus checks for vulnerable households or increased unemployment support. However, the implementation of this programme was a source of much criticism due to its potentially inflationary impact.²

Another major programme presented by Joe Biden, and approved in November 2021, was the Infrastructure Investment and Jobs Act, with a budget of 1.2 trillion dollars to be spent over the next five years on projects for improving classic infrastructure (such as roads, bridges and the railway network), public transport and internet access, with environmental considerations incorporated into most of the investments. However, of this 1.2 trillion total, only just under half represents new expenditure, as the rest will be financed through other existing infrastructure programmes. After one year of the programme, according to data from the White House, 185 billion dollars have already been disbursed.

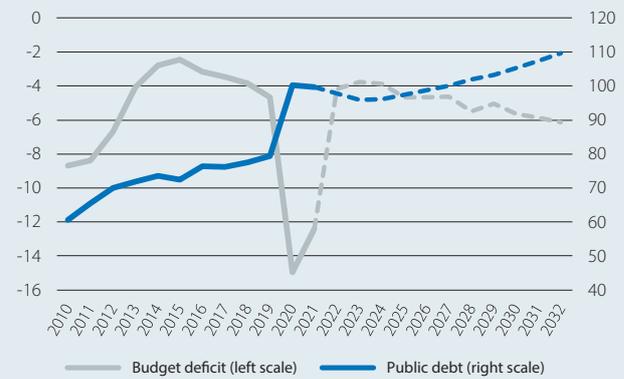

Finally, the Biden administration wanted to present a highly ambitious plan to tackle climate change. Under the name Build Back Better, this package did not gain the necessary support in Congress. Nevertheless, half a year later in August 2022, and renamed the Inflation Reduction Act, it did. In addition to the name, a key difference between the two plans is the fact that the original one involved an increase in the budget deficit in order to finance the investments, whilst the second one incorporates fiscal savings and tax-collection measures (such as imposing a minimum corporation tax rate of 15%). Thus, the investments in energy security and support measures to curb climate change (such as tax credits to finance investment in clean energy) are less than the fiscal savings and the increase in revenues envisaged under this plan. In total, the Biden administration expects to invest 433 billion dollars over the next 10 years and raise some 739 billion, which represents a saving of over 300 billion dollars in the budget deficit over the next decade. However, the outstanding disbursements under all these plans could be subject to changes in the framework of a divided

Congress³ and given the pending negotiations on matters such as the debt ceiling.

After all, reducing the budget deficit will not only help to ease the inflationary pressures, but it will also help to achieve more sustainable public finances. As can be seen in the last chart, the US has a structural budget deficit which causes its debt-to-GDP ratio to increase year after year. Thus, according to estimates by the Congressional Budget Office, this ratio will most likely continue to rise over the next decade, and in an environment of higher interest rates, the cost for American citizens will be higher.

Ricard Murillo Gili

2. At the time, prior to the outbreak of the war in Ukraine, headline and core inflation stood at 1.7% and 1.3%, respectively, but GDP had just reached the pre-pandemic level. Although the high inflation observed since then can be attributed to multiple factors (such as the global energy shock, the bottlenecks exacerbated by China's zero-COVID policy, or a highly dovish monetary policy throughout 2021), direct fiscal aid measures certainly played a role.

3. These support measures have raised some suspicions in Europe, as leaders in the region consider it could constitute subsidies for US industry, damaging European exports.

The EU: raider of the lost fiscal rules

30 years ago, the countries that founded the EU committed themselves to restricting and coordinating their fiscal policies with a common set of rules, best known for the debt and deficit limits of 60% and 3% of GDP. The aim was to avoid negative externalities between the public accounts of individual states and the consequent risks of financial instability.¹ These reasons are still valid today, but the rules have become outdated following a global financial crisis, a sovereign debt crisis in Europe, and a pandemic.² In fact, despite having been adjusted over the years,³ the rules finally had to be formally suspended in March 2020.

The reform proposed by the European Commission

In this context, last November the European Commission presented a proposal to reform the fiscal rules with a view to their re-implementation in 2024. The proposal does not change the debt and deficit targets of 60% and 3% (they are laid down in the EU treaties and changing them is rather infeasible); instead, it establishes them as medium-term targets and focuses on reforming the system to steer us towards them. In particular, the Commission proposes placing at the heart of the system a series of «structural fiscal plans», which would be drawn up at the national level and would revolve around three major axes: (i) investment priorities, (ii) structural reforms, and (iii) a fiscal path. Taken together, these three pillars would serve as the basis for assessing each state's debt and ensuring its sustainability.

In more detail, each national government would draw up its «structural fiscal plan» based on a four-year time horizon. The Commission would evaluate the plan and discuss it with the country in question, before approval is

1. The formation of the EU increased the degree of «substitutability» among the sovereign bonds of the different countries. The benefits (costs) of a good (bad) fiscal policy at the national level would thus have an impact on the rest of the countries. For example, a lavish country would face lower interest rates than it would suffer if it were outside the EU, but it would cause higher interest rates in the rest of the countries.
2. Among other shortcomings, the rules: (i) have failed to prevent the deterioration of public accounts which they sought to avoid, (ii) induce an overly procyclical fiscal policy which penalises investment, and (iii) are overly complex and based on variables that cannot be observed (e.g. the output gap or the structural balance). See the Focus «[A step towards a reform of the fiscal rules in Europe?](#)» in the MR03/2020 and «[European fiscal rules: an end to the 60% limit?](#)» in the MR03/2021.
3. See the Dossier «[The EU in 2022: fiscal rules reform back on the table](#)» in the MR12/2021. For example, a set of medium-term budgetary objectives (MTOs) were introduced, which the 2005 reform of the Stability and Growth Pact called for to be maintained throughout the business cycle in order to provide margin for manoeuvre in times of recession. Another example is the «1/20 rule» relating to debt reduction, which was introduced as part of the so-called «six-pack» of 2011, requiring countries to cut their excess debt above 60% of GDP by one twentieth each year. For a country with a debt ratio of 160% today, this would require primary surpluses of over 3% for the next 20 years.

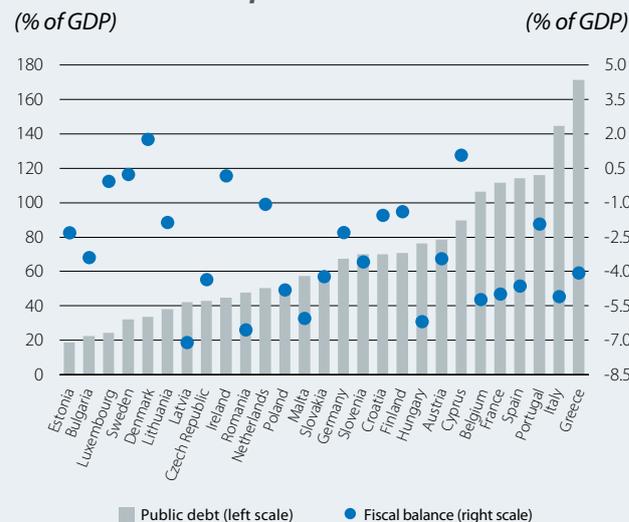

finally sought from the European Council. The fiscal path that would guide the evolution of the public accounts would be defined on the basis of a net primary expenditure rule,⁴ adjusting to the specific situation of each state and its debt sustainability analysis. Once in place, the plans would be monitored and evaluated, both by the Commission and by the independent fiscal authority of each country. Moreover, given this personalised approach, it would be necessary to establish a common framework with a clear set of rules and transparent criteria to guide the evaluation of each country's public accounts.

Finally, the European Commission proposes to maintain the system of «excessive deficit procedures» (EDPs) for breaches of the 3% deficit target, as well as to extend the range of sanctions in the event of non-compliance (reducing the pecuniary damage in order to make their implementation more credible, but accentuating the reputational damage). In the event of extraordinary economic events, the plan also envisages the activation of escape clauses to freeze the rules (at both the European and the country level).

Factors to consider and next steps

Firstly, the Commission is moving away from the uniformity of the current rules in favour of a more personalised approach to the sustainability of each

EU-27: state of the public accounts in 2022

Source: CaixaBank Research, based on data from the European Commission (European Economic Forecast, autumn 2022).

4. That is, spending net of discretionary income, and excluding interest payments and disbursements related to cyclical fluctuations in unemployment, such that the rule would not interfere with the functioning of automatic stabilisers.

European Commission proposal to reform the EU's fiscal rules

Starting point	The current rules (deficit of 3%, debt of 60%, debt correction rate of 1/20) are suspended until the end of 2023.
Medium-term targets	Deficit < 3% of GDP. Debt < 60% of GDP.
How to achieve the targets	National structural fiscal plans based on: <ul style="list-style-type: none"> • Investment plans. • Structural reforms. • Fiscal path.
Structural fiscal plans	<ul style="list-style-type: none"> • Fiscal path based on a net primary expenditure rule. • 4-year time horizon to place debt on a declining path and to bring the deficit < 3% (+3 additional years conditional on reforms). • Bilateral negotiation with the European Commission and subsequent approval by the European Council. • Monitoring by the national independent authorities for fiscal responsibility and the European Commission.

Source: CaixaBank Research, based on the European Commission's communication of 09/11/2022.

country's debt. This is a vision that is much better suited to the current environment and in particular to the disparity that exists between the public accounts across the EU (see chart).

Moreover, the Commission presents a broader view of debt sustainability, explicitly stating that it also depends on investment and reforms (i.e. on an economy's ability to grow and its resilience). In this regard, the new rules would help create space for fiscal policy. In other words, the sustainability of the public accounts is a constraint which fiscal policy must adhere to, but it is not its primary objective. Fiscal policy must help to stabilise the business cycle,⁵ and it can also help to foster stronger, more resilient and more inclusive long-term economic growth.⁶

Thirdly, the proposal simplifies the current fiscal framework (e.g. the use of indicators based on unobservable variables, such as structural deficits, would no longer be mandatory). However, it does so in a limited way and, given that many details are yet to be defined, it remains to be seen whether the final version will really involve less complexity and uncertainty.

On the downside, the time horizons appear somewhat generous: the plans would allow up to four years for the fiscal path to bring the deficit below 3% and for debt to be placed on a sustainably downward trajectory. Moreover, this timeframe could be extended by another three years depending on the country's reform and investment programme. Thus, the plan would likely extend beyond the mandate of the current government, which means that adhering to it would require a high degree of national commitment, as well as commitment, coordination, and legitimacy among all the actors

5. Especially in a monetary union, given that there is only one central bank and it cannot cope with idiosyncratic shocks between different countries.

6. e.g. by facilitating the energy and digital transitions.

involved (governments, independent fiscal authorities, the European Commission and the Council).

In any case, it is worth acknowledging the Commission's ambition: at a time when there is no consensus among the major European capitals on how to reform the fiscal rules, it has proposed a reform which goes far beyond marginal adjustments. Beginning in December, Member States must employ the same level of ambition in their negotiations, and when the fiscal rules are reinstated in 2024, they should incorporate a redesign that reflects the lessons of the past 30 years and which fits Europe's current reality.

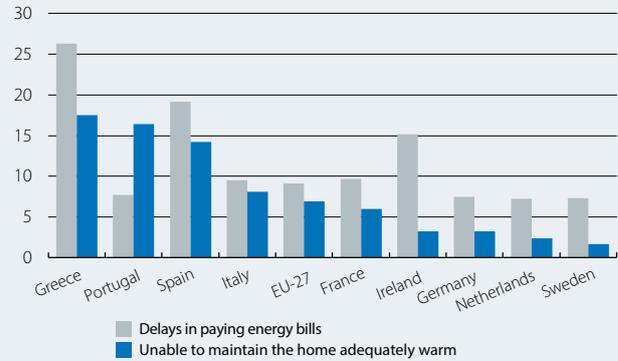

European household energy bills in the bleak midwinter

The energy crisis has led to an increase in energy prices which is not affecting all households alike, since their resources and initial situation are not the same in all cases. In this article, we analyse the level of energy poverty among European households and how the portion of household budgets spent on energy bills has increased in 2022.

A household is considered to be in a situation of energy poverty when it cannot meet all of its energy needs.¹ This situation is not only price-dependent, but is the result of a combination of three factors: low income, high expenditure on energy services (relative to income), and low energy efficiency in homes. Thus, measuring the energy poverty of households is no easy task, as we need to analyse multiple elements and there is no single measure that summarises the situation. Two indicators from surveys of household living conditions which do a reasonable job of summarising the problem are households' inability to keep their home adequately warm and delays in paying their energy bills.² In the EU, 6.9% of households were unable to keep their homes at an adequate temperature in 2021 and 6.4% were late in paying their energy bills. However, there are significant differences in these two measures from country to country, and there is generally a higher percentage of households in difficulty in southern Europe (see first chart).

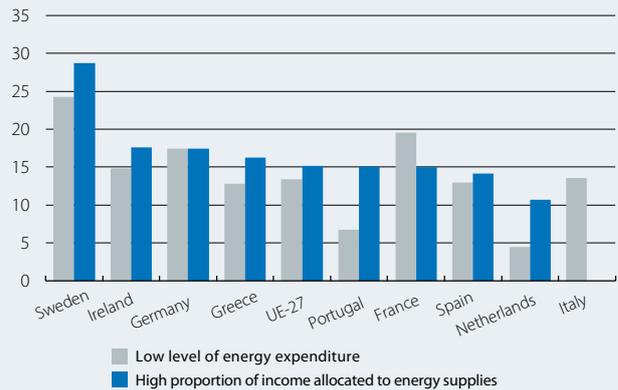

Another way to analyse energy poverty is by looking at expenditure on energy bills, as this can reveal difficulties in meeting household energy needs.³ In the EU-27, 13.4% of households had a level of energy expenditure that was below half the national median (in 2015, the latest year with comparable available information), which may be an indication of what is often referred to as «hidden energy poverty». On the other hand, if we measure energy expenditure as a proportion of household income, we see that 15.1% of households had an energy expenditure to income ratio of over twice the national median, a level generally considered «disproportionate». In both metrics, the dispersion among European countries is less pronounced, indicating that energy poverty measured on the basis of household spending was more similar between countries.⁴ In Spain, the situation in both metrics in 2020 had not changed substantially from the 2015 data: 10.3% of households had a very low level of expenditure (13.0% in 2015) and 16.8% of households

EU: energy poverty based on self-assessment in surveys
(% of households)

had a level that was disproportionate to their income (14.2% in 2015).

As we can see, energy poverty is a multidimensional phenomenon, so it is not easy to estimate how the current crisis is affecting each element. Measures such as the inability to keep the home adequately warm depend, above all, on the household already being in a precarious situation to begin with. Therefore, according to simulations by the European Commission,⁵ the rally in energy prices due to the current crisis is having a

2. EU Energy Poverty Hub of the European Commission.
3. EU Energy Poverty Hub of the European Commission.

4. Sweden would be an exception, with worse levels of energy poverty when measured on the basis of expenditure, although on the other hand it scored better in the other measures (maintaining the home at an adequate temperature and delays in paying bills).
5. See B. Menyhért (2022). «The effect of rising energy and consumer prices on household finances, poverty and social exclusion in the EU». Publications Office of the European Union. Luxembourg, doi:10.2760/418422, JRC130650.

relatively small impact on this aspect. On the other hand, these higher prices are having a more substantial impact on the measures related to the level of expenditure.⁶

Energy bills are rising, but not equally in every country

We focus our analysis of the impact of rising energy bills on the euro area's four major economies (Germany, France, Italy and Spain).⁷

For context, in 2020 households in France spent 4.8% of their income on energy bills, while in Germany the figure was 5.6% and in Italy and Spain, around 6.0%. From this starting point, energy prices have sky-rocketed (+72% increase since 2021), although the extent of the increase has been somewhat uneven between countries: up to September 2022, in France prices have risen by 40%; in Germany, by more than 60%; in Spain, by around 70%, while in Italy prices have almost doubled.⁸ This means that, in 2022, households' annual energy bills have increased by an average of around 500 euros in France, some 800 euros in Spain, over 1,000 euros in Germany and around 1,400 euros in Italy. As such, households are having to allocate a significantly larger portion of their income to paying their energy bills. Moreover, the divergence between countries has widened significantly: French households are still the ones allocating the smallest portion to their energy bills, at 6.5% of their income, while in Germany they spend almost 9.0%, in Spain just over 10% and in Italy, more than 12%.⁹

These estimates show how, in all countries, households are having to allocate a greater portion of their income to cope with the increase in their energy bills. Lower-income households will have the greatest difficulties

6. The expenditure-based energy poverty variables used in the second chart are measures of the relative position of household spending. Therefore, according to calculations by the European Commission, given that the price increase is fairly similarly for everyone, the relative position between them does not change very much.

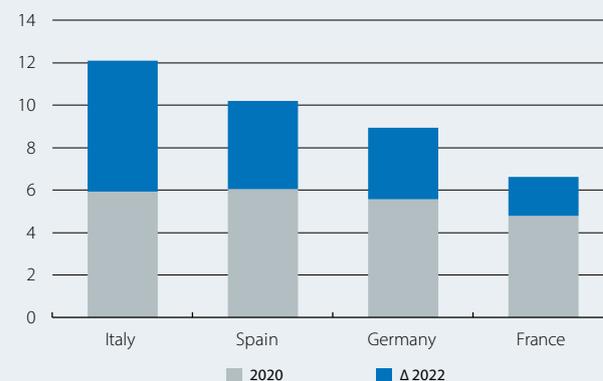

7. For this simulation, we obtain from the Household Budget Survey (HBS) published by Eurostat the composition of expenditure by income tranches in 2020 for all countries except Italy, where we use the same statistics published by its statistics office (ISTAT). The income indicators are obtained from the Income and Living Conditions (ILC) Survey, also published by Eurostat, in all cases. To estimate household expenditure on energy, we use the component CP045 «Electricity, gas and other fuels» from the HICP. This component already encompasses the general impact of the government measures implemented to reduce energy bills (e.g. VAT cuts), but not the specific aid for more disadvantaged groups.

8. These divergences are due, among other factors, to the composition of each country's energy consumption. For example, Italy has the highest exposure to gas, a commodity which saw its price increase by a factor of 17: around 31% of its direct energy consumption corresponds to gas, and more than 56% of electricity generation is based on gas (22% and 35% on average in Europe, respectively).

9. These estimates measure how much it would cost to achieve the same level of energy consumption as in 2020 (i.e. they do not take into account possible reductions in energy consumption).

Expenditure on electricity, gas and other fuels, by country

(% of household income)

in paying their energy bills, so it is key that support measures are targeted in order to reach all these struggling households. This aid must also be accompanied by incentives for energy saving. In this regard, price signals remain an essential element for reducing demand as much as possible and for encouraging European households to save energy in the bleak midwinter

The Spanish economy performs better than expected in the closing stages of the year

The Spanish economy continues to slow, but is holding up better than expected in the adverse context, introducing upward biases into our GDP forecast for Q4 2022 (-0.3% quarter-on-quarter vs. +0.2% in Q3). The indicators for the last quarter of the year provide mixed signals. On the one hand, there is a cooling in domestic spending, dented by the deterioration in real income, and a worsening of the Purchasing Managers' Index (PMI) in the industrial sector. On the other hand, the labour market is holding up better than expected, with job creation slightly dampened but still positive, while the tourism sector remains buoyant and is very close to recovering pre-pandemic levels, with the weakness of one of our biggest source markets – Germany – being offset by the strength of others. Another good piece of news is the containment of inflation. Thanks to the correction in electricity and gas prices, it has now registered four consecutive months of declines, placing it at 6.8% in November, the lowest rate since January.

The weakening of economic activity is less pronounced than expected. The cooling of activity is especially evident in industry, which is more susceptible to the supply shocks that have been affecting the economy, whereas services are holding up very well. In particular, the manufacturing sector's PMI, hampered by the heightened uncertainty as well as the increased energy, transport and commodity costs, remains in contractionary territory (45.7 points in November) due to a drop in production and a shrinking order book. However, the services PMI climbed back above 50 points in November, reaching 51.2 points, the highest level since July, thanks to stronger than expected demand. Household spending, meanwhile, remains very weak but is declining at a slower rate than before, and retail purchases – excluding service stations and in real terms – registered the smallest decline in five months in October (-0.6% year-on-year vs. -1.8% in Q3 2022).

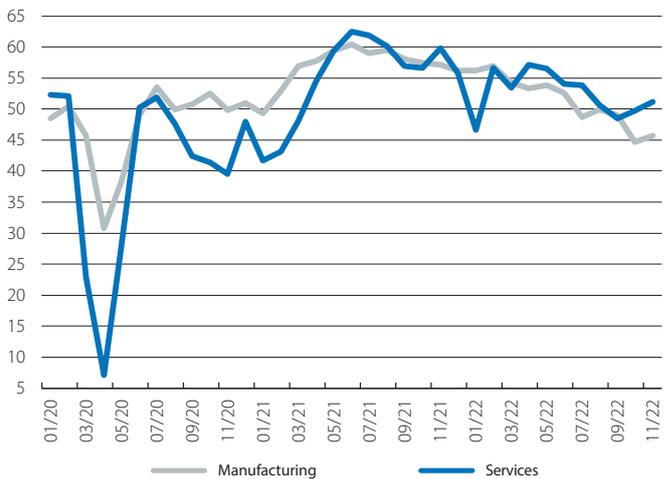

The labour market remains resilient. The pattern in employment in recent months remains positive, despite the current adverse economic scenario. Social Security affiliation numbers fell very slightly in November, by just 155 workers, which represents a significant improvement compared to the usual trend in that month (an average decline of 23,200 people in the period 2014-2019). In seasonally adjusted terms, this was the biggest monthly increase in the last year (77,695), meaning that the seasonally-adjusted number of registered workers not on furlough has grown by 0.5% in Q4 so far, compared to 0.7% in Q3, marking a slower decline than we had anticipated. As for registered unemployment, the figures are once again better than expected, with a fall of 33,512 people; this is the biggest decrease in a month of November in the last decade, except for in 2021 when it was affected by the recovery of employment after the pandemic.

Inflation continues to fall, driven by the drop in energy prices. According to the leading indicator, headline inflation moderated to 6.8% in November (7.3% in October). This was mainly due to the fall in electricity prices as the decline observed in late October continued throughout November, thanks to benchmark gas prices remaining contained, lower levels of electricity generation at gas-fired power plants and a higher number of consumers paying the surcharge to offset the gas price cap. The fall in fuel prices has also played a role in this moderation, albeit to a lesser extent, as the price of a barrel of Brent oil registered a 6.5% monthly reduction in November, bringing it to 89 euros. However, in the other components of the CPI, the increases in production costs are still being transmitted to final prices. Therefore, core inflation, which excludes energy and unprocessed foods, rose slightly in November to 6.3%.

The recovery in tourism revenues is offsetting the sharp deterioration in the foreign energy deficit. Up until last September, the current account balance had a surplus of 1,376 million euros, 77.9% less than a year earlier (6,224 million). This deterioration is mainly explained by the widening of the deficit in the balance of goods, which increased to 53,437 million euros, four times higher than in the same period last year (-13,267 million). On the one hand, the energy deficit continues to rise and reached an all-time peak in the period January-September (-39,480 million vs. -18,007 million in 2021), as a result of the sharp rise in import prices (up 70.5% year-on-year). However, the balance of non-energy goods has also deteriorated, registering a deficit of 13,957 million (compared to a surplus of 4,740 million in 2021), as a result of greater import growth (27.4% vs. 19.8% in the case of exports), which was also driven by a sharp price rally (18.3%).

On the upside, and thanks to the excellent summer season, the tourism sector registered a cumulative surplus of 39,356 million euros for the first nine months of the year. The data for October remain encouraging: the number of foreign tourist arrivals is gaining momentum, approaching 7.2 million, and they spent almost 8.3 billion euros. This narrows the gap versus the levels of the same month in 2019 to 5.4% and 0.3%, respectively (-11.6% and -3.9% in September). Overnight stays in hotels by foreign tourists also improved, with the figure as of October lying 6.3% below that of October 2019 (-8.2% in the previous month).

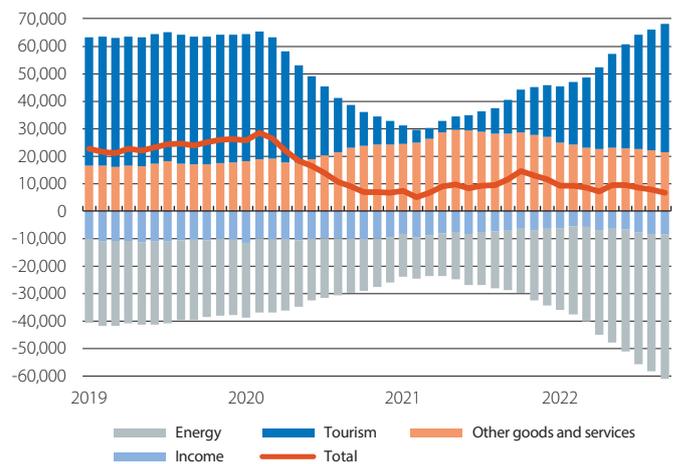

There are growing signs of cooling in the housing market. In Q3 2022, home values based on appraisals stagnated in quarter-on-quarter terms, having registered meagre growth in the previous quarter (0.4%); in year-on-year terms, there has been a sharp slowdown over the course of 2022 to 4.7% in Q3, 2 points less than in Q1. Housing demand is also beginning to run out of steam: the number of sales rose by 6.9% year-on-year in September, compared to rates in excess of 30% in the first few months of the year; however, in cumulative terms for the last 12 months, a total of 644,000 sales have been completed, marking the highest figure since 2008.

Evolution of household financial assets in nominal and real terms in Spain

Increase in savings in nominal terms since the pandemic

In this article, we analyse the purchasing power of the stock of Spanish households' financial assets¹ in a context of high inflation.

In 2020 and 2021 there was a significant increase in savings among Spanish households. In particular, the COVID-19 restrictions and lockdowns made it difficult for households to spend their money on in-person activities (such as tourism and leisure), while at the same time the support from economic policies softened the decline in gross disposable income – it fell by just 2.0% year-on-year in 2020, and by 2021 it was already back above the pre-pandemic level.

In this context, the stock of households' financial assets² increased by over 224 billion euros between the end of 2019 and Q2 2022. This is a vast increase; to put it in context, between the end of 2015 and the end of 2019 the stock of assets rose by 119.9 billion, far short of the increase of the last two and a half years.

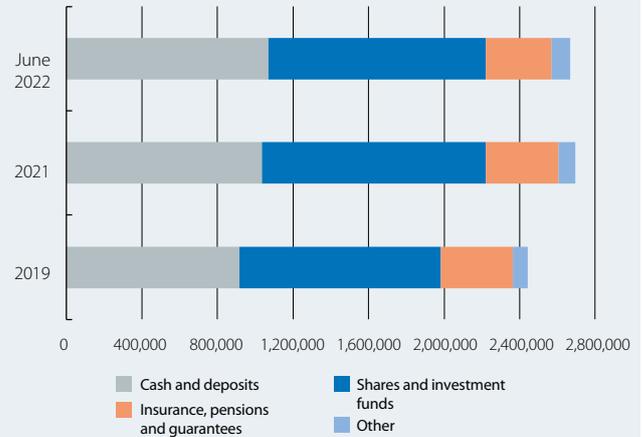

This growth corresponds to an acquisition of assets of 229 billion euros and a revaluation effect of –8 billion. The savings accumulated by households during the pandemic have played a significant role in this increase in financial assets:³ in view of the restrictions on leisure and social activities, households opted to acquire more financial assets. Specifically, in each year between 2015 and 2019, Spanish households acquired financial assets worth an average of 2.6% of their gross disposable income. This figure rose to 14.9% in 2020 and 9.1% in 2021, and in the first two quarters of 2022 it was still above the average of those same quarters in the years prior to the pandemic. In fact, if we compare the observed level of acquisition of financial assets between the end of 2019 and Q2 2022 with the «theoretical» acquisition that would have occurred over the same period if households had allocated the same percentage of their disposable income as they did in 2015-2019, then the «excess» acquisition of these assets amounts to more than 150 billion euros.

Inflation has eroded households' financial wealth

A 224-billion-euro increase in the stock of financial assets seems high, but we have to bear in mind that we are in

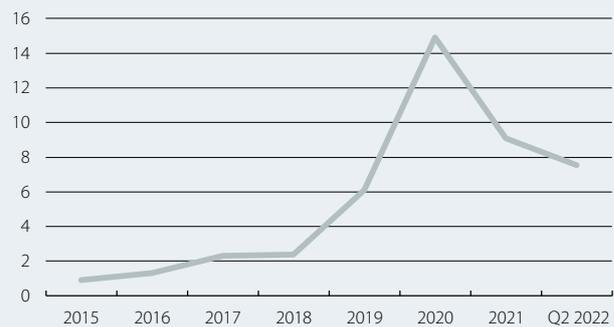

1. Throughout this article, when we talk about households we are including non-profit institutions serving households (NPISHs).
 2. Gross financial assets, i.e. we do not take into account the stock of financial liabilities, which has remained fairly stable since the pandemic.
 3. However, a portion of the savings amassed during the pandemic were spent on acquiring real estate rather than financial assets, resulting in an «over-investment» in non-liquid assets.

Spain: households' financial assets (EUR millions)

Source: CaixaBank Research, based on data from the Bank of Spain.

Spain: household financial savings rate * Acquisition of financial assets/GDI (%)

Notes: * Unlike the standard savings rate, which is determined based on the portion of gross disposable income (GDI) which is not allocated to final consumption expenditure, the financial savings rate includes only the portion of savings that is allocated to the acquisition of financial assets. We use the ratio of this acquisition divided by GDI.

Source: CaixaBank Research, based on data from the Bank of Spain.

an inflationary context in which rising prices have significantly eroded the value of assets in real terms. Indeed, the accumulated inflation between the end of 2019 and Q2 2022 amounts to 12.4%. In particular, by deflating the stock of financial assets in order to assess their value in real terms, we see that it is clearly lower in Q2 2022 than it was at the end of 2019 (see third chart). This is despite the significant increase in the stock in nominal terms. Thus, the significant increase in these assets driven by the savings amassed during the pandemic has not prevented a fall in the stock of assets in real terms.

In other words, the increase in the stock of financial assets in nominal terms has not been sufficient to prevent a loss of their purchasing power due to the high inflation. In addition, it should be borne in mind that the increase in financial wealth may have been concentrated

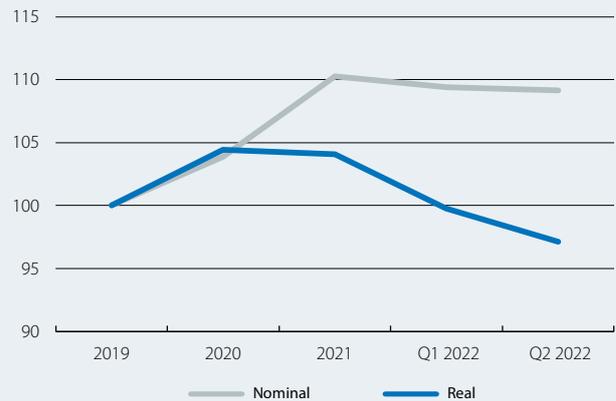

among those with higher incomes, who have a greater capacity to save and a lower propensity for consumption, as suggested by an analysis conducted by CaixaBank Research on the savings accumulated during the pandemic, based on internal data.⁴

This simple exercise has significant implications in the complex economic context in which we currently find ourselves. Firstly, while the savings accumulated during the pandemic will cushion the fall in consumption, it seems that it will not be enough to prevent a contraction in consumption in real terms. In particular, if we analyse the historical relationship between real consumption and its main determining factors (gross disposable income, the stock of financial assets and other relevant macroeconomic variables such as inflation, interest rates and home prices, etc.), we see that consumption is very likely to register a negative growth rate next year. This consumption forecast is consistent with a moderate fall in the savings rate in 2023, which makes sense insofar as we believe that precautionary saving in the face of the heightened uncertainty ought to largely mitigate the fall in the savings rate.

Javier García-Arenas

4. See the article «[To borrow or not to borrow: a dilemma that depends on what was saved during the pandemic](#)» in the MR11/2021. In particular, this article shows that in the case of households on low and medium-low incomes (the first two income quintiles), in 2021 they will have already consumed all the excess savings which they accumulated during 2020 due to the pandemic.

The evolution of Spanish households' electricity bills in 2022

This year remained extremely convulsive in the energy markets, with significant pressure on prices – accentuated by the war in Ukraine – and the consequent intervention of the markets to try to defuse it.¹ But how did the electricity bills of Spanish households evolve? We analyse this question based on individual CaixaBank customers' direct debit electricity bill payments.²

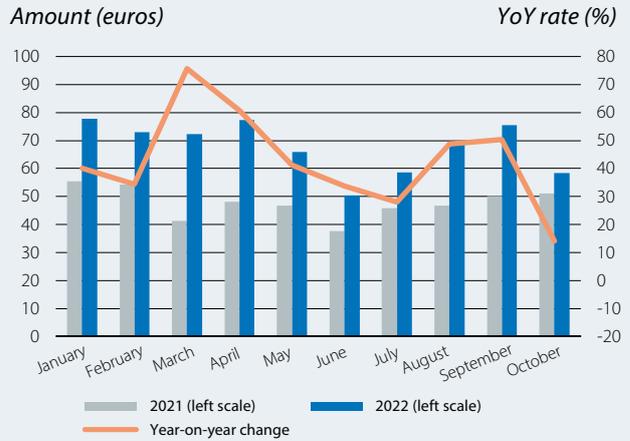

In a previous article,³ we found that price changes in the wholesale electricity market spread more quickly to electricity bills on a regulated tariff (PVPC) than to those on a free-market tariff, which usually have a fixed price for the duration of the contract.⁴ Thus, while the median regulated-tariff bill increased by 32% year-on-year in Q4 2021, in the case of the free-market tariff it fell by 14%, as the price increases were not yet being passed on to consumers but the first relief measures implemented for households were.

The analysis of bills in 2022 shows that households on a regulated tariff have continued to experience highly volatile and high electricity bills, while fixed-tariff bills (which account for around two-thirds of the total)⁵ have gradually increased as more and more contracts have been renewed. More specifically, the median bill in the regulated market is 68 euros in 2022 (the average between January and October); this is 20 euros higher than in the previous year, but with significant fluctuations ranging from +14% in October to +75% year-on-year in March (+42% on average), as a consequence of the movements in the wholesale market.

In contrast, the year-on-year increases of household bills based on fixed-price contracts have gradually risen as the year progressed. In January 2022, the average bill was 60 euros, 27% less than a year earlier. By the spring, bills were already at roughly the same level as a year earlier (0% year-on-year growth). In October 2022, in contrast, the average bill reached almost 80 euros, representing a year-on-year growth of +21%.

For 2023, we expect electricity bills to remain high, although there is great deal of uncertainty linked to the gas market and regulatory developments. Household bills in the regulated market will be higher than the

previous year, considering that the price of MIBGAS futures for 2023 are slightly higher than in 2022 (+8.2% on average), although the gas price cap may partially offset these increases in the first half of 2023. In any event, the volatility of regulated-market bills will be reduced after the planned PVPC tariff reform is introduced. Households on a free-market tariff whose contracts are renewed will see their bills go up, continuing the trend observed in 2022, although the increases could begin to moderate from Q2 2023 onwards.⁶ The respite in electricity bills will come, but we do not expect this to happen before the end of 2023.

Josep Mestres Domènech and Alberto Graziano

1. For further details, see D. Rodríguez Rodríguez (2022). «Un año de intervenciones regulatorias en electricidad y gas: un análisis de situación». Fedea (content available in Spanish), <https://documentos.fedea.net/pubs/ap/2022/ap2022-27.pdf>.

2. We analyse the amounts of individual customers' direct debit electricity bill payments each month (we exclude companies and self-employed workers) and we differentiate between customers on a free-market tariff and those on a regulated tariff (PVPC).

3. See the Focus «[Electricity prices are sky high, but what about household bills?](#)» in the MR01/2022.

4. For further details on how Spain's retail electricity market works, see the Focus «[The Iberian electricity market and the price rally in Spain](#)» in the MR01/2022.

5. According to CNMC data, in Q3 2021 35.1% of households had regulated-market contracts and 64.9% had free-market contracts.

6. In the past, it has taken around 12 months for changes in the price trend of the regulated market to spread to the free market.

Which sectors are behind the strength of the Spanish labour market?

One of the most positive aspects of the current economic scenario is the resilience shown by the labour market, which has exceeded pre-pandemic employment levels since mid-2021. In this context, it is worth asking what lies behind the strong performance. One way to determine the factors that explain this pattern is to disaggregate job creation among the main branches of economic activity, in order to assess whether the improvement is widespread and thus responds to general factors; or whether, on the contrary, it is concentrated in certain sectors and is due to specific factors.

The statistics on registered workers according to the Ministry of Inclusion, Social Security and Migration (MISSM) show a 4.5% year-on-year increase in the number of Social Security affiliates in the year to date (January to November). The first chart details the sectors showing the most buoyancy in terms of job creation in that period, with the best performers being hotels and restaurants, leisure and entertainment, information and telecommunications, professional and scientific activities, real estate activities, and transport and storage.

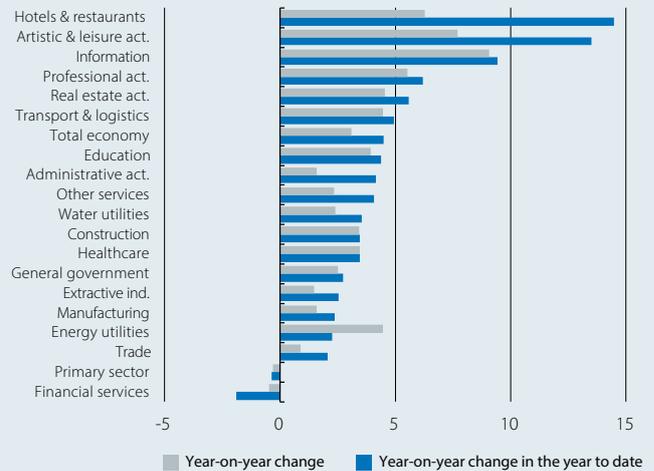

In this regard, the breakdown by sector reflects the fact that the current buoyancy in the labour market is driven, on the one hand, by the revival of sectors which depend on social interaction after emerging from the pandemic (sectors associated with tourism and leisure); and, on the other hand, those sectors related to the new post-COVID normal, with a strong revival in housing demand (real estate activities), an acceleration in digitalisation processes (associated with professional activities or information and telecommunications) and greater penetration of e-commerce (related to transport and logistics).

On the other hand, the sections performing the worst include financial activities (due to the gradual consolidation of the financial sector), the primary sector (adversely affected by the energy crisis and adverse weather), the energy and utilities industries (weighed down by the rising energy prices) and trade (due to weak consumption in the face of rising inflation), which are the activities most affected by the challenges that have dominated the economic scenario in recent months.

Looking ahead to the next few months, given that most sectors have been gradually recovering previous employment levels (see second chart), which sectors could contribute the most to job creation? To analyse this point, we must investigate which sectors were the most dynamic in terms of job creation prior to the outbreak of

the pandemic, and also see how the sectoral structure of the labour market has changed since the beginning of the last decade, reflecting possible changes in the productive structure. To this end, we use the same breakdown by sector and compare the change in their weight relative to the total number of registered workers between 2010 and 2022 by producing a breakdown between different periods (see third chart). Specifically, the changes between 2010 and 2019 (blue bar) reflect the long-term pre-pandemic trends, while the changes

from 2019 to 2022 reflect those caused by the pandemic (grey bar).¹

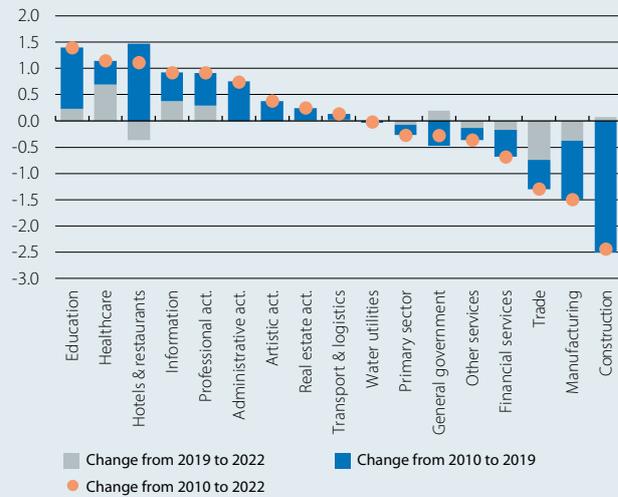

Firstly, it is worth noting that the sector that has grown the most in terms of relative weight over the period 2010-2022 (orange dot) is education, with a 1.4-pp increase, followed by the healthcare and hotels and restaurants sectors, both registering a 1.1-pp increase. The first sector is a reflection of the proliferation of educational activities in the private sector in Spain in recent years.² The second one is largely a direct consequence of the pandemic (it is the sector that has grown the most in relative weight between 2019 and 2022), but it is also a response to the growing need for care workers as a result of the Dependency Act and, more generally, the gradual ageing of the Spanish population. The third reflects the exceptional performance of Spain's tourism sector in the previous decade, with new highs in the number of tourist visits registered in 2019 (the sector went from 53 million visitors to more than 83 million in 2019); although it is clear that the pandemic dealt the sector a heavy blow (the grey bar is negative) due to the international mobility restrictions. Finally, the information and telecommunications, professional activities and administrative activities sectors also stand out, as to some degree they are all related to digitalisation and the growth of e-commerce and teleworking – processes which have been set in motion in recent years but were accelerated by the pandemic.

At the other end of the spectrum, the role of the construction sector in the labour market has shrunk, as a result of the profound consolidation of the sector following the real estate boom that occurred during the previous business cycle (from the 1990s to the mid-2000s). The role of the manufacturing industry has also reduced significantly, not only due to the gradual tertiarisation of the economy, but also because much of the decline in the number of registered workers has occurred in the auxiliary construction industry (ceramics and glass) and in the manufacture of metal products and furniture, all of which are also associated to some degree with the reduced role of the construction sector.

On balance, the analysis by sector and by period allows us to conclude that the sectors that are now showing

Spain: difference in relative weight in the total number of S.S. affiliates

more buoyancy are not only those directly affected by the consequences of the pandemic (hotels and restaurants, leisure and healthcare), but they are also those which had gained the most relative weight in the previous decade. Indeed, these trends of the last decade have, in most cases, been accentuated in the new post-pandemic normal, namely: the rise of e-commerce, the greater penetration of teleworking and the ageing of the population.

Pedro Álvarez Ondina

1. For 2022, we use the cumulative data available up to November. In addition, the analysis excludes the sectors related to international organizations, extractive industries, energy utilities, gas, steam and air conditioning supplies, water utilities and household activities, as they account for a modest portion of the total registered workforce and have undergone very little change in the last decade.

2. According to data on teaching staff and other personnel in non-university educational establishments maintained by the Ministry of Education and Vocational Training, the workforce in private education grew by 19% between the 2009-2010 and 2019-2020 academic years, compared with a 5% increase in the case of public-sector education.

Portugal, mixed signals at the end to the year

The strength of economic activity in Q3 is confirmed, but there are growing signs of a slowdown. It has been confirmed that in Q3 2022 GDP grew by 4.9%, with positive contributions from both domestic and foreign demand of 2.9 and 2.0 pps, respectively. In the short term, we expect to see a slowdown in economic activity, especially over the winter months, due to the impact of the higher energy prices and higher financing costs. This slowdown is already evident in some indicators, such as the daily economic activity indicator calculated by the Bank of Portugal, which in mid-Q4 2022 was suggesting a stagnation in year-on-year terms. The confidence indicators for November, meanwhile, suggest that households will continue to exercise caution in their consumption decisions. However, the deterioration in expectations appears to have bottomed and there are no signs of any further deterioration, as reflected by the 3-percentage-point improvement in the economic climate indicator in November versus the previous month.

Inflation fell in November to 9.9%. Portugal's inflation followed the trend of the euro area and moderated in November, according to the National Statistics Institute's preliminary estimate, falling to 9.9% from 10.1%. This was driven by a correction in the energy component (-1.49% monthly), which in turn was the result of movements in international oil prices – the price of Brent slid to 89 euros on average, 6.5% less than in October. However, prices in the rest of the components of the CPI basket are picking up, as rising production costs gradually spread to final prices, as reflected in the rise in core inflation. While we are comfortable with our forecast for average inflation in 2022 (7.9%), we believe it is still too early to declare that the peak of this inflationary cycle is behind us.

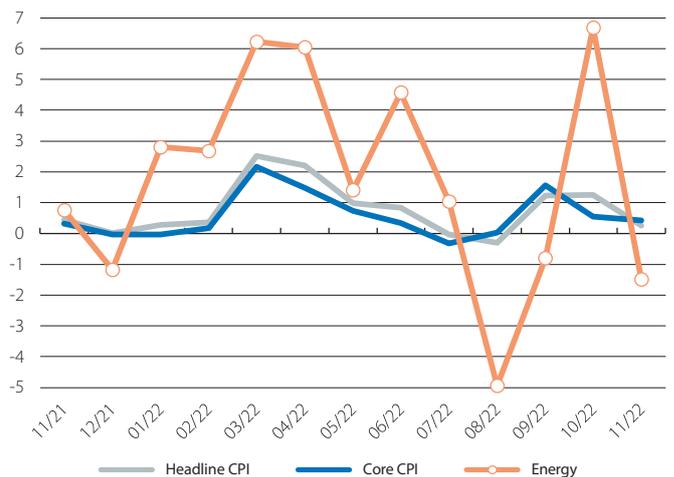

Labour market: first signs of a setback? According to the National Statistics Institute data for October, the employed population declined slightly in monthly terms (-0.2%; -8,000 people), although it is still up in year-on-year terms (+0.7%; +36,200 people); the unemployment rate, meanwhile, remained at 6.1% for the second consecutive month. Other statistics, however, invite more caution: registered unemployment for October rose by 0.7% on a monthly basis, the third increase in as many months. Of particular note is the monthly rise in unemployment in construction (+1.5%), as this differs from the trend observed in the years prior to the pandemic: unemployment in this sector normally rises in December and January, possibly due to weather conditions, whereas this year it has increased in September and October; moreover, in the four years prior to the pandemic, unemployment in the sector registered an average decline of 2.7% per month in October. A similar pattern is apparent in the real estate sector and in administrative and auxiliary services (+1% vs. -0.9% on average in the four years prior to the pandemic). These patterns appear to reflect the first signs of economic slowdown, driven by the energy crisis, the tightening of financial conditions and the high uncertainty.
